Search

URL parameters or query string parameters are used to send a piece of data from client to server via a URL. They can contain information such as search queries, link referrals, user preferences, etc.

JavaScript has a default class URL used to handle everything about URLs, including the parameters.

You can make a URL instance from any URL string you wish. If you want to access the URL of the current web page a user is browsing, you can use window.location.toLocaleString(). Otherwise, you can use any link.
